

10MHz, RRIO, CMOS Operational Amplifier for Cost-Sensitive Systems

General Description

ET85602 is a dual low-voltage (1.8 V to 5.5 V) operational amplifier (op amp) with rail-to-rail input- and output-swing capabilities. The device is highly cost-effective solutions for applications where low-voltage operation, a small footprint, and high capacitive load drive are required. Although the capacitive load drive of the ET85602 is 100 pF, the resistive open-loop output impedance makes stabilizing with higher capacitive loads simpler. The op amp is designed specifically for low-voltage operation (1.8 V to 5.5 V).

ET85602 is specified for the extended industrial/automotive temperature range (-40°C to +125°C). It is available in SOP8 / MSOP8 / TSOT23-8 packages.

Functional Description

Operating Voltage

ET85602 operates from 1.8 V to 5.5 V, is unity-gain stable, and is designed for a wide range of general-purpose applications.

Rail-to-Rail Input

The input common-mode voltage range extends 100 mV beyond the supply rails for the full supply voltage range of 1.8 V to 5.5 V. This performance is achieved with a complementary input stage.

Rail-to-Rail Output

Designed as a low-power, low-voltage operational amplifier, the ET85602 delivers a robust output drive capability. A class AB output stage with common-source transistors achieves full rail-to-rail output swing capability. For resistive loads of 10 kΩ, the output swings to within 15 mV of either supply rail, regardless of the applied power-supply voltage. Different load conditions change the ability of the amplifier to swing close to the rails.

Absolute Maximum Ratings

Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. These are only stress ratings, and functional operation of the device at these or any other conditions beyond those indicated under recommended operating conditions are not implied. Exposure to absolute maximum rated conditions for extended periods may affect device reliability.

Layout Guidelines

For best operational performance of the device, use good PCB layout practices, including:

Place the external components as close to the device as possible. This configuration prevents parasitic errors (such as the Seebeck effect) from occurring.

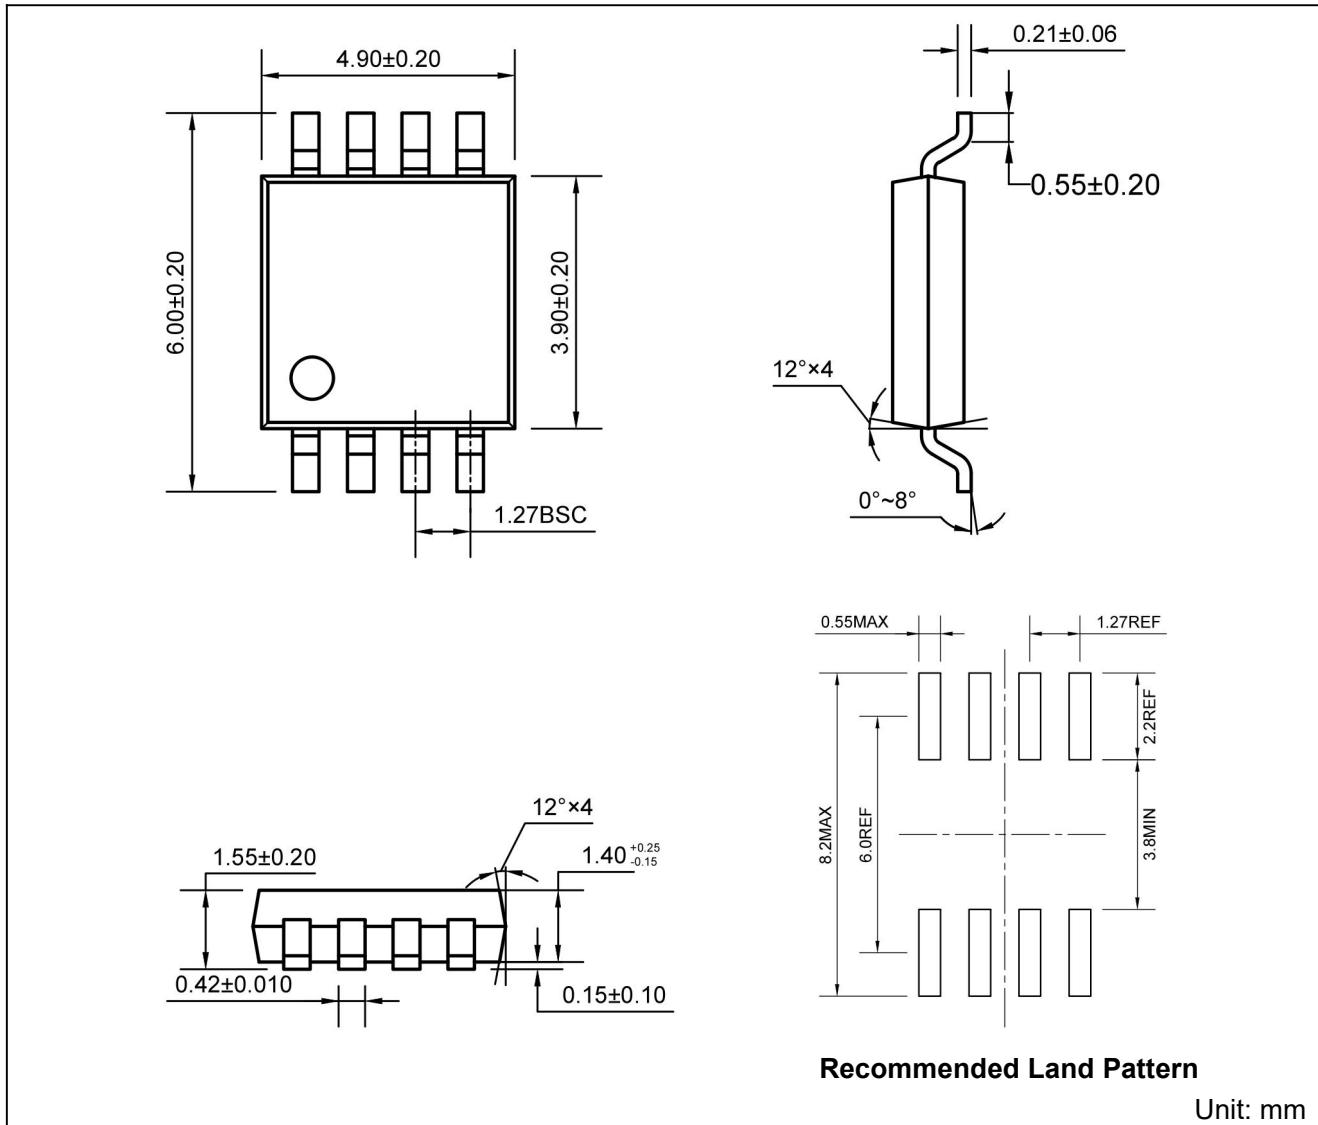

To reduce parasitic coupling, run the input traces as far away from the supply lines and digital signal as possible. Low-ESR, 0.1 μF ceramic bypass capacitors must be connected between each supply pin and ground, placed as close to the device as possible. A single bypass capacitor from V+ to ground is applicable to single supply applications.

Consider a driven, low-impedance guard ring around the critical traces. A guard ring can significantly reduce leakage currents from nearby traces that are at different potentials.
