

ET64B16V - 16 bit I²C-bus/SMBus I/O Expander

General description

The ET64B16V is a 16-bit general purpose I/O expander that provides remote I/O expansion for most micro-controller families via the I²C-bus interface.

ET64B16V has four pairs of 8-bits registers: configuration register, input register, output register and polarity reversal register.

When power-on, all I/O ports are configured to input status. By configuring the I/O ports' configuration register, the system can determine the input and output status of each I/O port. Each input or output data is stored in the corresponding input or output register. The polarity of input registers can be flipped by configuring polarity reversal registers to save external logic gates.

When time-out or error operation occurs, the host can reset ET64B16V by applying a low level on $\overline{\text{RESET}}$ Port. When power on reset, all registers are in default state, and I²C BUS/SM BUS state machine is initialized.

When any input state is different from its corresponding input register state, the ET64B16V open drain interrupt ($\overline{\text{INT}}$) output is active to indicate to the host that the input state has changed.

The $\overline{\text{INT}}$ can be connected to the interrupt input of the micro-controller. By sending the interrupt signal, the micro-controller port is informed that there is data entering, instead of passing through I²C BUS.

The Port P output of ET64B16V can provide 25mA perfusion current, which can directly drive LED.

The hardware address pin (A1、A0) can be used to program and change the I²C BUS address.

Features

- I²C-BUS to parallel port expander
- Operating power supply voltage range of 1.65 V to 5.5 V
- Low standby current consumption
 - 1.5uA typical at V_{DD}=5V
 - 1.0uA typical at V_{DD}=3.3V
- Schmitt-trigger action allows slow input transition and better switching noise immunity at the SCL and SDA inputs
 - V_{HYS} = 0.15 V (typical) at V_{DD}=1.8 V
 - V_{HYS} = 0.20 V (typical) at V_{DD}=2.5 V
 - V_{HYS} = 0.26 V (typical) at V_{DD}=3.3 V
 - V_{HYS} = 0.45 V (typical) at V_{DD}=5 V
- 5 V tolerant I/O ports
- Active LOW reset input $\overline{\text{RESET}}$
- Open-drain active LOW interrupt output ($\overline{\text{INT}}$)

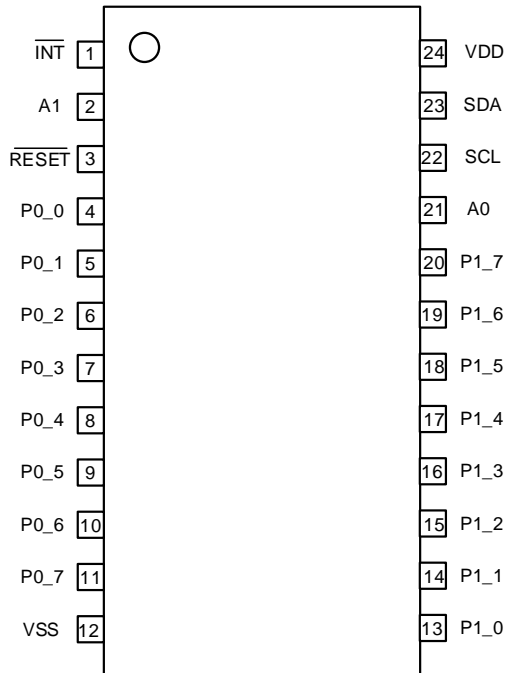

ET64B16V

- 400 kHz Fast-mode I²C-BUS
- Internal power-on reset
- Power-up with all channels configured as inputs
- Noise filter on SCL/SDA inputs
- Outputs with 25 mA drive maximum capability for directly driving LEDs
- Latch-up performance exceeds 100mA
- HBM ESD protection exceeds ± 2000 V
- CDM ESD protection exceeds ± 1000 V
- MSL 3

ET64B16V

Pin. Function

Pin Name	Pin No.	Description
INT	1	Interrupt output. Connect to VDD through a pull-up resistor.
A1	2	Address input1. Connect directly to VDD or VSS.
RESET	3	Active LOW reset input. Connect to VDD through a pull-up resistor if no active connection is used.
P0_0	4	Port 0 input/output 0.
P0_1	5	Port 0 input/output 1.
P0_2	6	Port 0 input/output 2.
P0_3	7	Port 0 input/output 3.
P0_4	8	Port 0 input/output 4.
P0_5	9	Port 0 input/output 5.
P0_6	10	Port 0 input/output 6.
P0_7	11	Port 0 input/output 7.
VSS	12	GND pin.
P1_0	13	Port 1 input/output 0.
P1_1	14	Port 1 input/output 1.
P1_2	15	Port 1 input/output 2.
P1_3	16	Port 1 input/output 3.
P1_4	17	Port 1 input/output 4.
P1_5	18	Port 1 input/output 5.
P1_6	19	Port 1 input/output 6.
P1_7	20	Port 1 input/output 7.
A0	21	Address input0. Connect directly to VDD or VSS.
SCL	22	Serial clock bus. Connect to VDD through a pull-up resistor.
SDA	23	Serial data bus. Connect to VDD through a pull-up resistor.
VDD	24	Supply voltage pin.

Block Diagram

Figure 2. Block Diagram

Functions Description

BUS Transactions

The ET64B16V is an I²C-bus slave device. Data is exchanged between the master and ET64B16V through write and read commands using I²C-bus. The two communication lines are a serial data line (SDA) and a serial clock line (SCL). Both lines must be connected to a positive supply via a pull-up resistor when connected to the output stages of a device. Data transfer may be initiated only when the bus is not busy.

Chip Address

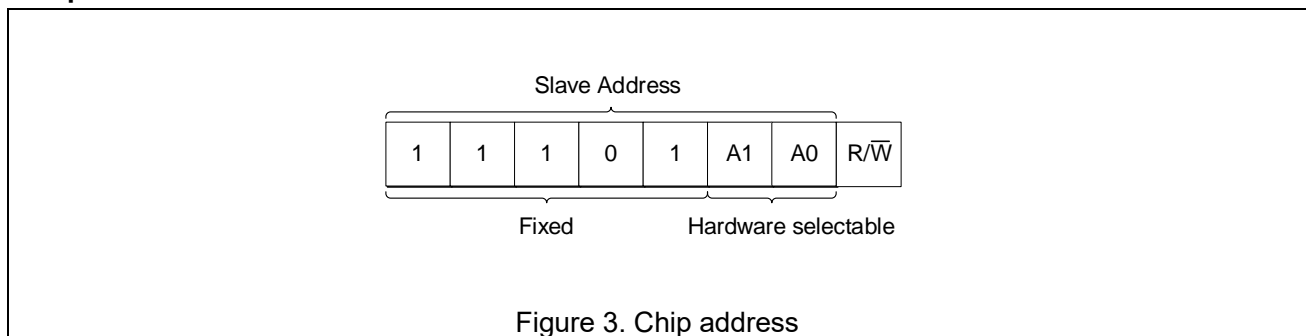

Figure 3. Chip address

ADDR(A0,A1) is the hardware address package pin and is held to either HIGH (logic 1) or LOW (logic 0) to assign one of the four possible slave addresses. The last bit of the slave address (R/W) defines the operation (read or write) to be performed. A HIGH (logic 1) selects a read operation, while a LOW (logic 0) selects a write operation.

ET64B16V

Write Commands

Data is transmitted to the ET64B16V by sending the device address and setting the Least Significant Bit (LSB) to a logic '0'. The command byte is sent after the address and determines which register receives the data that follows the command byte.

The eight registers within the ET64B16V are configured to operate as four register pairs. The four pairs are input Registers, output Registers, polarity inversion and configuration Registers. After sending data to one register, the next data byte is sent to the other register in the pair. For example, if the first byte is sent to Output Registers1 (register 3), the next byte is stored in Output Registers0 (register 2).

There is no limit on the number of data bytes sent in one write transmission. In this way, the host can continuously update a register pair independently of the other registers or the host can simply update a single register.

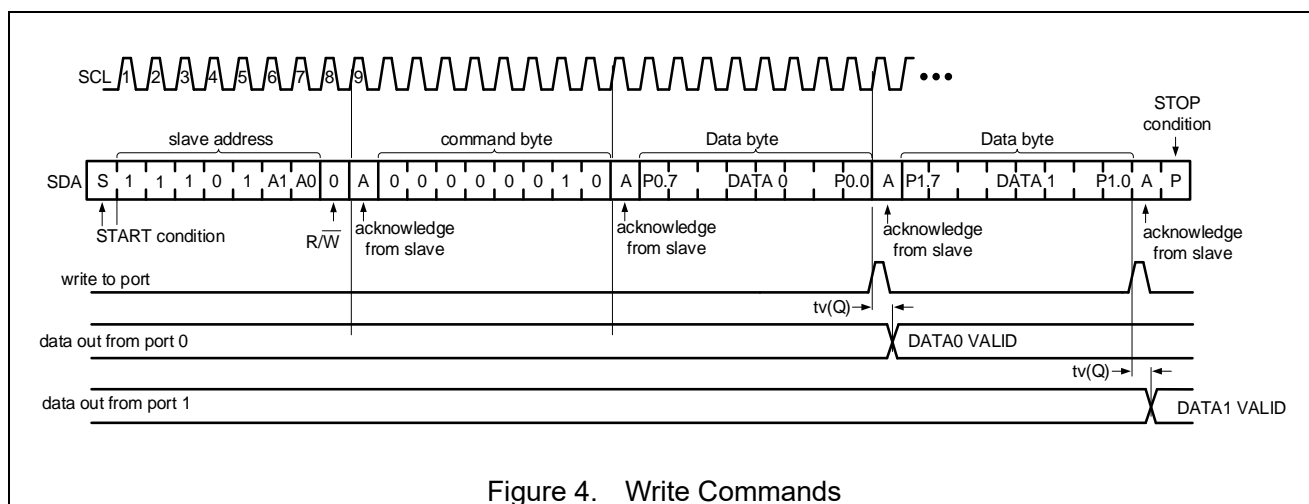

Figure 4. Write Commands

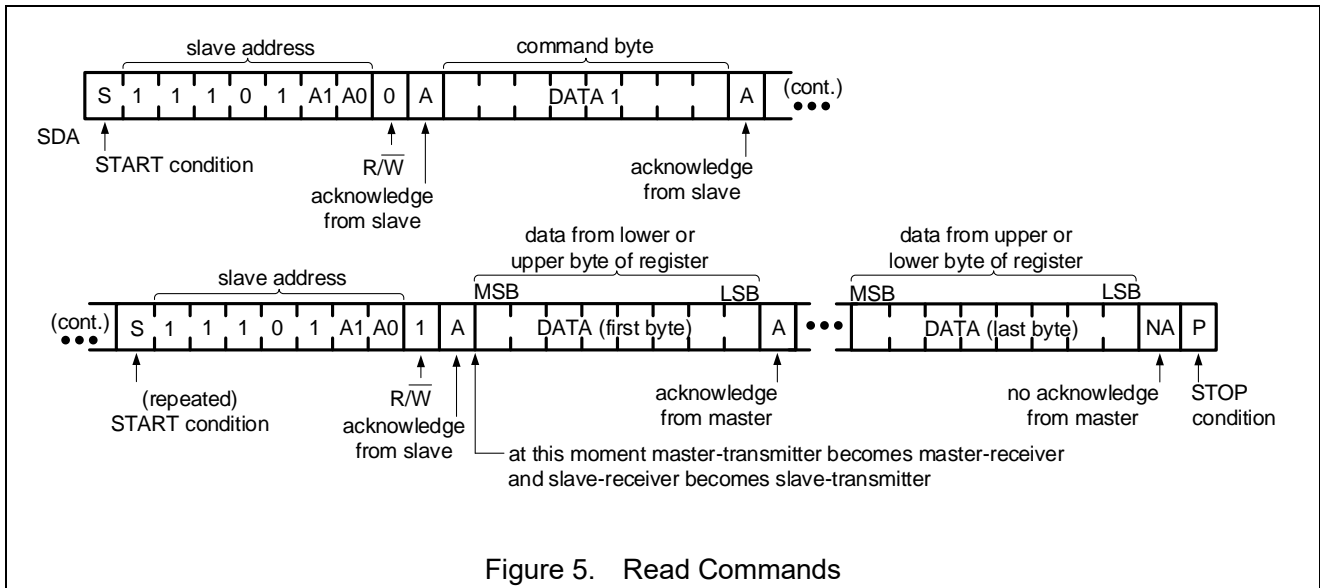

Read Commands

To read data from the ET64B16V, the bus master must first send the ET64B16V address with the least significant bit set to a logic '1'. The command byte is sent after the address and determines which register is to be accessed.

After a restart, the device address is sent again, but this time the least significant bit is set to a logic '1'. Data from the register defined by the command byte is sent by the ET64B16V. Data is clocked into the register on the rising edge of the ACK clock pulse. After the first byte is read, additional bytes may be read, but the data now reflects the information in the other register in the pair. For example, if Input Registers 1 is read, the next byte read is Input Registers 0. There is no limit on the number of data bytes received in one read transmission, but on the final byte received the bus master must not acknowledge the data.

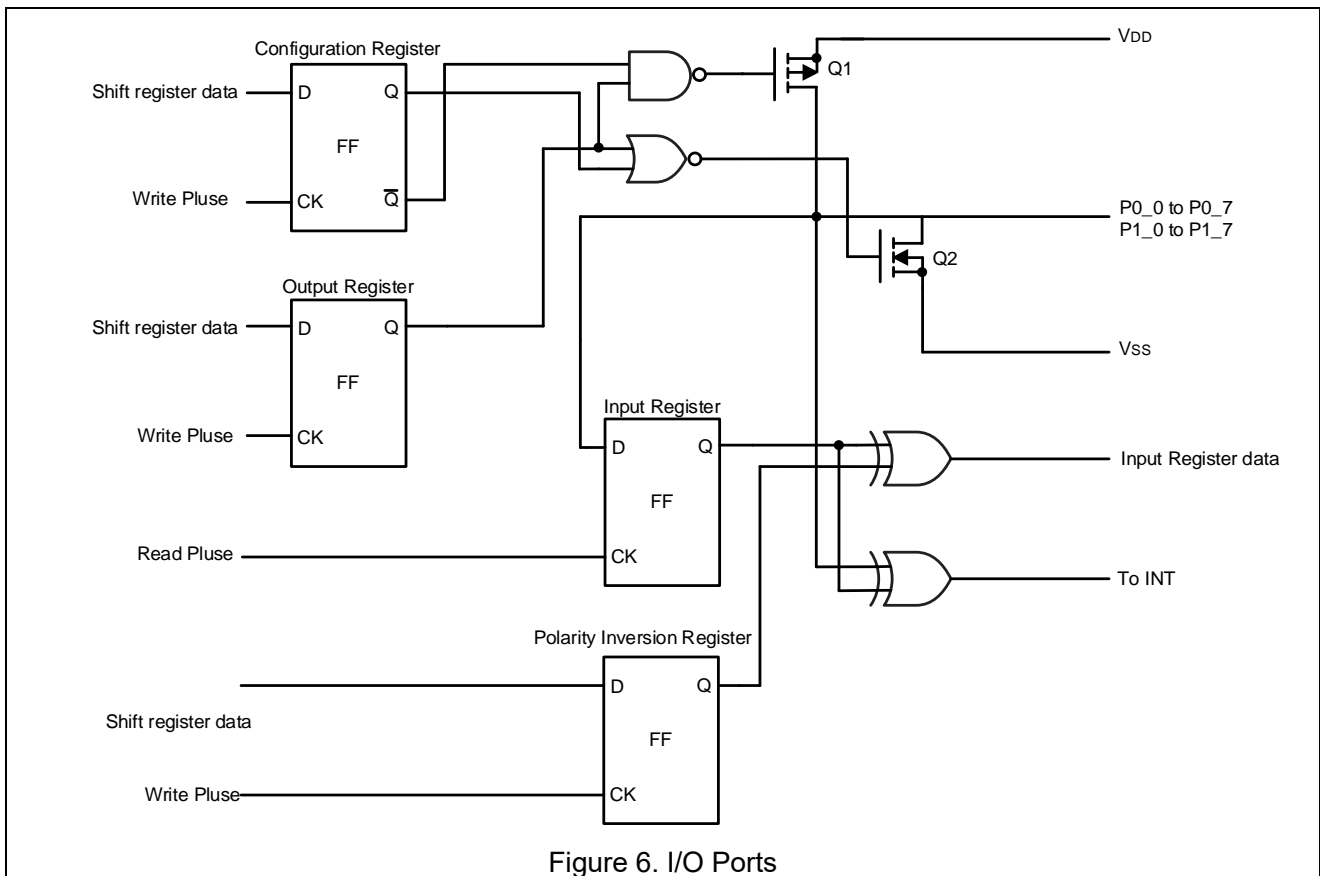

After a subsequent restart, the command byte contains the value of the next register to be read in the pair. For example, if Input Registers 1 was read last before the restart, the register that is read after the restart is the Input Registers 0.

ET64B16V

I/O Port

If the I/O is configured as an output, Q1 or Q2 is enabled, depending on the state of the Output port register. In this case, there are low-impedance paths between the I/O pin and either VDD or VSS. The external voltage applied to this I/O pin should not exceed the recommended levels for proper operation.

Power-on Reset

When power (from 0 V) is applied to VDD, an internal power-on reset holds the ET64B16V in a reset

ET64B16V

condition until VDD has reached VPOR. At that time, the reset condition is released and the ET64B16V registers and I²C-bus/SMBus state machine initializes to their default states. After that, VDD must be lowered to below VPOR and back up to the operating voltage for a power-reset cycle.

Reset Input ($\overline{\text{RESET}}$)

The $\overline{\text{RESET}}$ input can be asserted to initialize the system while keeping the VDD at its operating level. A reset can be accomplished by holding the $\overline{\text{RESET}}$ pin LOW for a minimum of $t_{w(\text{rst})}$. The ET64B16V registers and I²C-bus/SMBus state machine are changed to their default state once $\overline{\text{RESET}}$ is LOW (0). When $\overline{\text{RESET}}$ is HIGH (1), the I/O levels at the P port can be changed externally or through the master. This input requires a pull-up resistor to VDD if no active connection is used.

Interrupt Output ($\overline{\text{INT}}$)

An interrupt is generated by any rising or falling edge of the port inputs in the Input mode. After time $t_v(\overline{\text{INT}})$, the signal $\overline{\text{INT}}$ is valid. The interrupt is reset when data on the port changes back to the original value or when data is read from the port that generated the interrupt. Resetting occurs in the Read mode at the acknowledge (ACK) or not acknowledge (NACK) bit after the rising edge of the SCL signal. Interrupts that occur during the ACK or NACK clock pulse can be lost (or be very short) due to the resetting of the interrupt during this pulse. Any change of the I/Os after resetting is detected and is transmitted as $\overline{\text{INT}}$.

A pin configured as an output cannot cause an interrupt. Changing an I/O from an output to an input may cause a false interrupt to occur, if the state of the pin does not match the contents of the Input Port register.

The $\overline{\text{INT}}$ output has an open-drain structure and requires pull-up resistor to VDD depending on the application. $\overline{\text{INT}}$ should be connected to the voltage source of the device that requires the interrupt information.

Interface definition

Byte	Bit							
	7(MSB)	6	5	4	3	2	1	0(LSB)
I ² C-BUS slave address	1	1	1	0	1	A1	A0	R/W
I/O data bus	P0.7	P0.6	P0.5	P0.4	P0.3	P0.2	P0.1	P0.0
	P1.7	P1.6	P1.5	P1.4	P1.3	P1.2	P1.1	P1.0

Pointer register and Command byte

Following the successful acknowledgement of the address byte, the bus master sends a command byte, which is stored in the Pointer register in the ET64B16V. The lower three bits of this data byte state the operation (read or write) and the internal registers (Input, Output, Polarity Inversion, or Configuration) that will be affected. This register is write only.

While a new command has been sent, the register that was last addressed continues to be accessed by reads until a new command byte is sent.

ET64B16V

Pointer Register Bits	Command Byte	Register	Protocol	Default Value
0000 0000	00h	Input Registers 0	Read only	xxxx xxxx

Input Registers (00H,01H)

The Input registers (registers 0 and 1) reflect the incoming logic levels of the pins, regardless of whether the pin is defined as an input or an output by the Configuration register. The Input port registers are read only; writes to these registers have no effect.

The default value 'X' is determined by the externally applied logic level.

Output Registers (02H,03H)

The Output registers (registers 2 and 3) shows the outgoing logic levels of the pins defined as outputs by the Configuration register. Bit values in these registers have no effect on pins defined as inputs. In turn, reads from these registers reflect the value that was written to these registers, not the actual pin value.

ET64B16V

Polarity inversion Registers (04H,05H)

The Polarity inversion registers (registers 4 and 5) allow polarity inversion of pins defined as inputs by the Configuration register. If a bit in these registers is set (written with '1'), the corresponding port pin's polarity is inverted in the input register. If a bit in this register is cleared (written with a '0'), the corresponding port pin's polarity is retained.

Configuration Registers (06H,07H)

The Configuration registers (registers 6 and 7) configure the direction of the I/O pins. If a bit in these registers is set to 1, the corresponding port pin is enabled as a high-impedance input. If a bit in these registers is cleared to 0, the corresponding port pin is enabled as an output.

Note: When the P port is suspended, configure it to the output state please.

Absolute Maximum Ratings

Symbol	Parameter	Conditions	Min	Max	Unit
V _{DD}	Supply voltage		-0.5	+6	V
V _I	Input voltage		-0.5	+6	V
V _O	Output voltage		-0.5	+6	V
I _{IK}	Input clamping current	A1,A0, $\overline{\text{RESET}}$, SCL; V _I < 0V	-	±20	mA
I _{OK}	Output clamping current	$\overline{\text{INT}}$; V _O < 0V	-	±20	mA
I _{IOK}	Input/output clamping current	P port, SDA; V _O < 0V or V _O > V _{DD} ,	-	±20	mA
I _{OL}	LOW-level output current	P port, SDA, $\overline{\text{INT}}$; V _O = 0V to V _{DD}	-	50	mA
		SDA, $\overline{\text{INT}}$; V _O = 0V to V _{DD}	-	25	mA
I _{OH}	HIGH-level output current	P port; V _O = 0V to V _{DD}	-	25	mA
I _{DD}	Supply current	through V _{SS}	-	200	mA
T _{STG}	Storage temperature		-65	+150	°C
T _{JMAX}	Maximum junction temperature		-	150	°C
R _{θJA}	Transient thermal impedance from junction to ambient	TSSOP24		88	°C/W

Note: Stresses above those listed in Absolute Maximum Ratings may cause permanent damage to the device. Functional operation at conditions other than the operating conditions specified is not implied. Only one Absolute Maximum rating should be applied at any one time.
